# Supplementary Material: Threshold Phases and the Limits of Motion Compensation for Event Streams

## S1. Clipping of Counts

Counts are clipped at $15$ before coding. On one-pixel voxels with $k \geq 3$, clipping removes less than $1\%$ of the events. At $k = 1$ it removes up to $6\%$ and on two-pixel voxels up to $28\%$, both by night. On the grid of two pixels and $T_0/3$ the clip costs up to $0.16$ of fidelity at night and at most $0.04$ of box fidelity.

## S2. Scaled Luma

In the lossy modes the luma is $16$ times the count. Coding this scaled luma without loss costs $1.9$ to $2.5$ times the bits of the unscaled lossless mode.

## S3. Operating Points on a Coarse Grid

On the grid of two pixels and $T_0/3$, x265 by day reaches $F = 0.975$ with $3.26$ bits per event at QP $14$, $0.933$ with $1.09$ at QP $28$, $0.840$ with $0.31$ at QP $36$ and $0.706$ with $0.051$ at QP $46$. On this grid the intra picture has the default QP offset of x265.
